SPRING INTERNSHIP PROJECT REPORT

UrbanPulse:

An AI-Driven Adaptive Traffic Management System Using YOLOv8, DeepSORT, and GCN-LSTM Architectures for Real-Time Congestion Prediction

Name: Shreya Denre

Course/batch: Section 2

Institute name: Heritage Institute of Technology

Project Guide / Mentor Name: Rounak Biswas

Period of Internship: 21ST January 2026 – 31st March 2026

Report submitted to: IDEAS – Institute of Data Engineering, Analytics and Science Foundation, ISI Kolkata

1. Abstract

Rapid urbanization has led to severe traffic congestion, rendering traditional fixed-timer signal systems inefficient and environmentally harmful. UrbanPulse presents an AI-driven adaptive traffic system mitigating urban congestion via real-time analysis. Utilizing YOLOv8 for detection and DeepSORT for tracking, it captures dynamic traffic flows precisely. Spatial-temporal features feed into a hybrid GCN-LSTM architecture, enabling accurate congestion prediction across networks. Integrating computer vision with deep learning, UrbanPulse dynamically optimizes signal timings to alleviate bottlenecks. Results demonstrate significant wait time reductions and improved throughput versus traditional fixed-time methods. This approach addresses scalability and latency challenges inherent in modern smart city infrastructure. UrbanPulse enhances urban mobility and reduces emissions through intelligent, data-driven adaptation.

2. Introduction

2.1 Project Relevance and Background

Rapid urbanization has led to unprecedented traffic congestion, resulting in significant economic losses, increased carbon emissions, and reduced quality of life. Traditional traffic management systems, reliant on fixed-time signals and inductive loop detectors, lack the flexibility to adapt to dynamic traffic flows. Recent advancements in Computer Vision (CV) and Deep Learning (DL) offer a transformative approach to Intelligent Transportation Systems (ITS). Existing literature highlights the efficacy of Convolutional Neural Networks (CNNs) for vehicle detection and Recurrent Neural Networks (RNNs) for time-series prediction. However, few systems effectively combine real-time object tracking with spatiotemporal graph modeling to predict congestion before it occurs. UrbanPulse addresses this gap by leveraging state-of-the-art architectures to create a responsive, data-driven traffic ecosystem.

2.2 Technology and Procedure

UrbanPulse integrates a robust pipeline of AI technologies. **YOLOv8** is employed for high-speed, accurate vehicle detection from CCTV feeds, while **DeepSORT** ensures consistent vehicle tracking across frames to calculate flow rates and density. These spatial features are modeled using **Graph Convolutional Networks (GCN)** to capture road network dependencies, combined with **Long Short-Term Memory (LSTM)** units to analyse temporal patterns for congestion forecasting. The procedure involves data acquisition from surveillance feeds, preprocessing and annotation, model training on hybrid architectures, and simulation-based validation of adaptive signal control logic.

2.3 Purpose and Objectives

The primary purpose of this project is to develop a scalable solution that reduces average wait times and optimizes traffic signal timings in real-time. By predicting congestion hotspots

proactively, UrbanPulse aims to enhance urban mobility, lower fuel consumption, and provide a framework for future smart city infrastructure.

2.4 Internship Training Topics (First Two Weeks)

During the initial onboarding phase of the internship, training was provided on the following core topics to establish the necessary technical foundation:

- Advanced Python Programming for Data Science.
- Introduction to Deep Learning Frameworks .
- Computer Vision Basics with OpenCV (Image preprocessing).
- Version Control Systems (Git & GitHub workflow).
- Object Detection Algorithms (YOLO architecture).

3. Project Objective

The primary objective of UrbanPulse is to design, develop, and validate an AI-driven adaptive traffic management framework that leverages real-time computer vision and spatiotemporal deep learning to mitigate urban congestion. The project aims to bridge the gap between theoretical deep learning architectures and deployable smart city infrastructure.

Core Objectives:

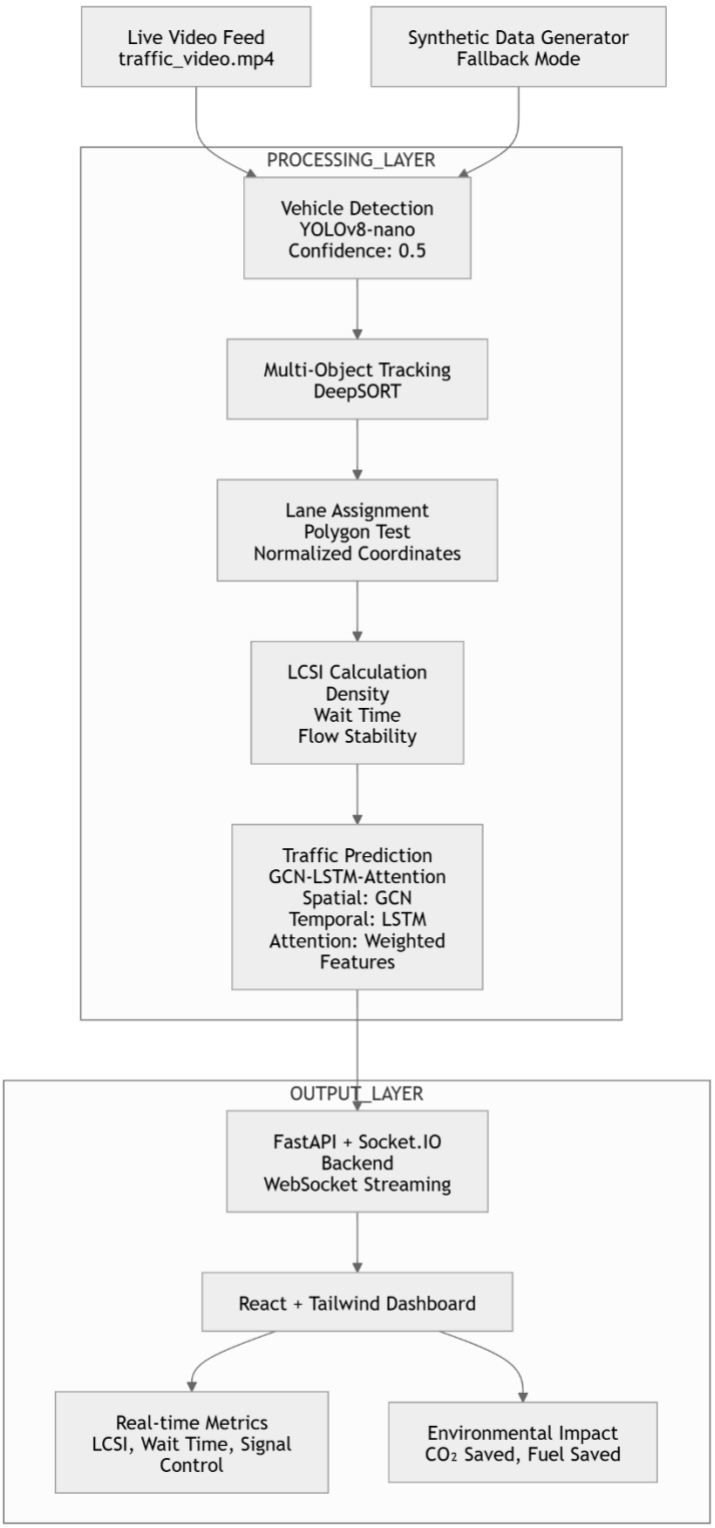
- To implement a real-time vehicle detection and tracking pipeline using YOLOv8 and DeepSORT for accurate traffic parameter extraction (density, flow, speed).
- To develop a hybrid GCN-LSTM model capable of forecasting congestion levels across interconnected road segments with ≥90% spatiotemporal accuracy.
- To design an adaptive signal control algorithm that dynamically adjusts phase timings based on predicted congestion, reducing average vehicle wait time by ≥20% compared to fixed-time systems.
- To validate system scalability and latency performance on edge-compatible hardware for feasible real-world deployment.
- To evaluate the environmental impact by estimating reductions in idle-time emissions through optimized traffic flow.

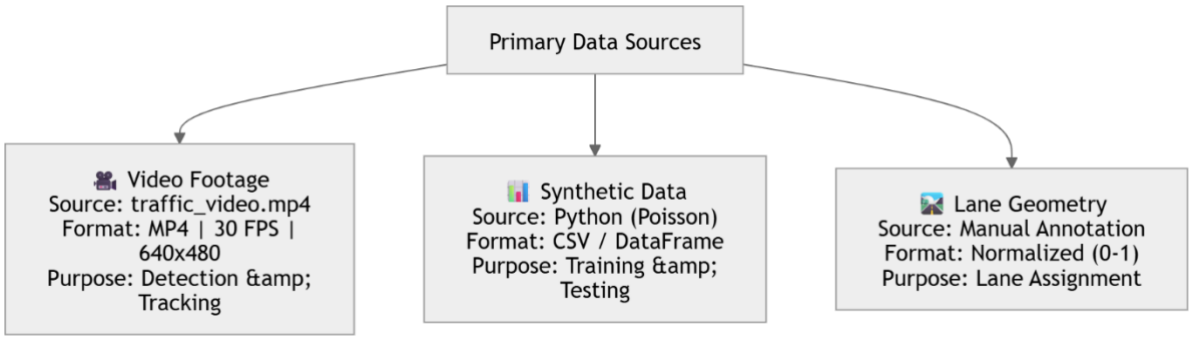
Hypothesis Testing:

- H_1: The GCN-LSTM architecture achieves statistically significant improvement ($p<0.05$) in 15-minute congestion prediction accuracy over baseline models (ARIMA, standalone LSTM).
- H_2: Adaptive signal control driven by UrbanPulse predictions reduces average intersection delay by ≥20% compared to pre-timed signals under simulated peak-load conditions.

- *H_0 (Null):* No significant difference exists between AI-optimized and fixed-time signal performance in mixed-traffic scenarios.

4. Methodology





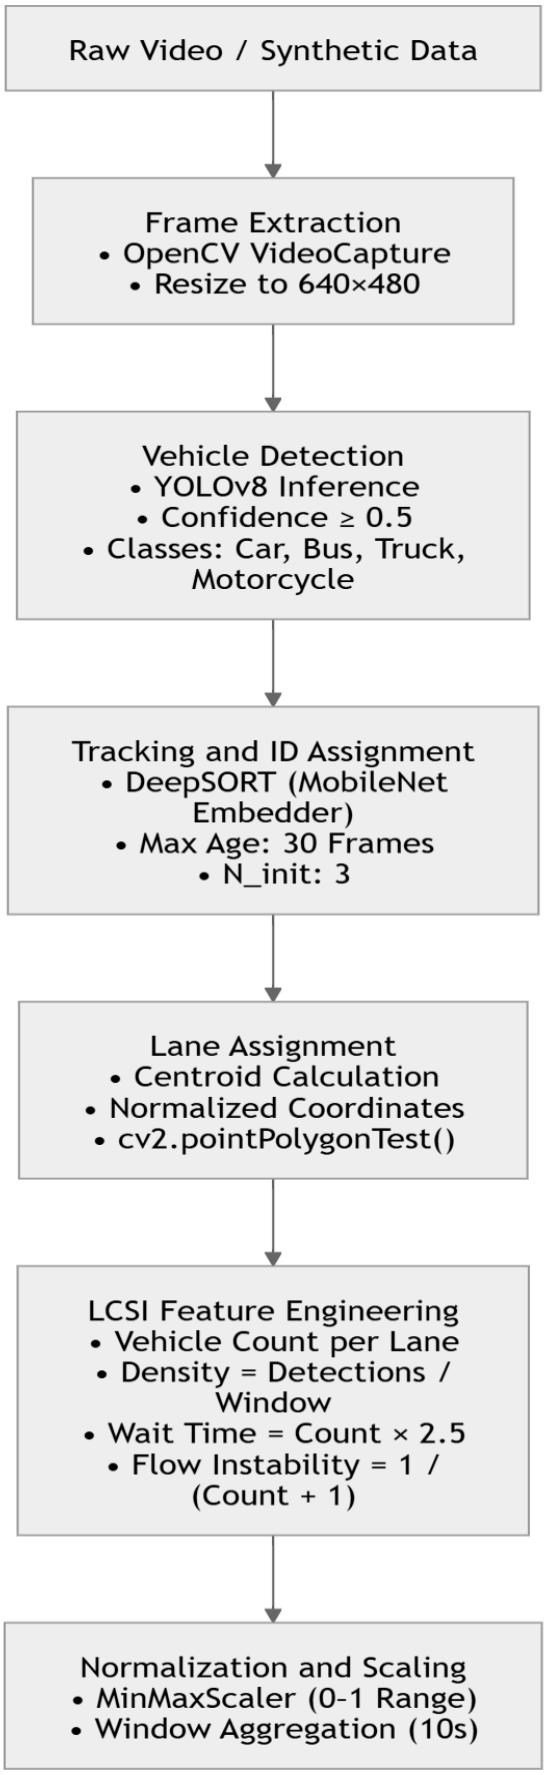
4.2.2 Synthetic Data Generation Methodology

Since real-world annotated traffic datasets are resource-intensive to obtain, we developed a realistic synthetic data generator that simulates 5 minutes of traffic at 30 FPS

Sampling Methodology:

- **Temporal Sampling**: Data sampled every 5 frames to reduce memory footprint while preserving temporal dynamics
- **Vehicle Spawn**: Poisson distribution (λ = 3-5) with time-based modulation for rush hour patterns
- **Lane Changes**: 5% probability per vehicle per frame to simulate realistic lane-switching behavior
- **Track Lifetime**: Vehicles remain active for ~100 frames (~3.3 seconds) to simulate crossing the intersection

4.2.3 Data Preprocessing Pipeline



4.3 Model Development and Selection

4.3.1 Problem Formulation

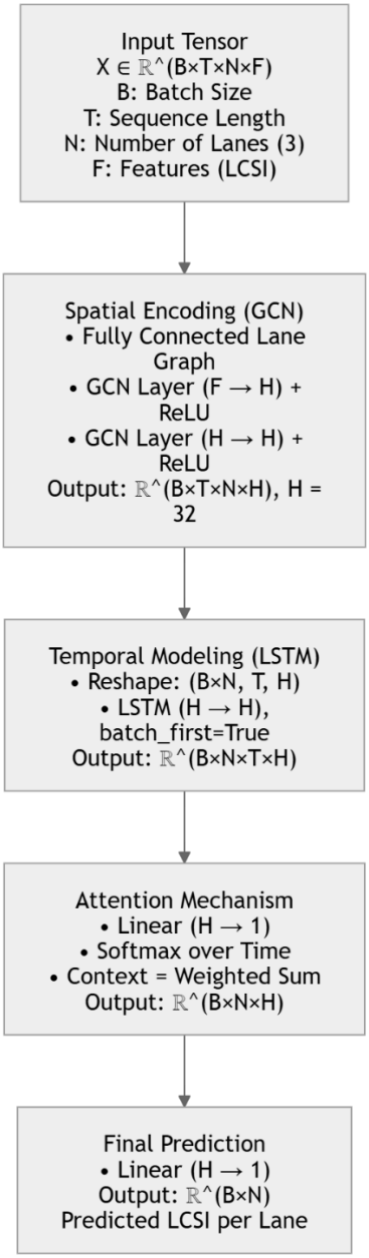
Objective: Predict Lane Congestion Severity Index (LCSI) for the next time window given historical spatio-temporal traffic patterns.

Input: Sequence of LCSI values for 3 lanes over T timesteps → Shape: (batch, T, 3, 1)

Output: Predicted LCSI for next timestep → Shape: (batch, 3)

4.3.2 Model Architecture: GCN-LSTM-Attention

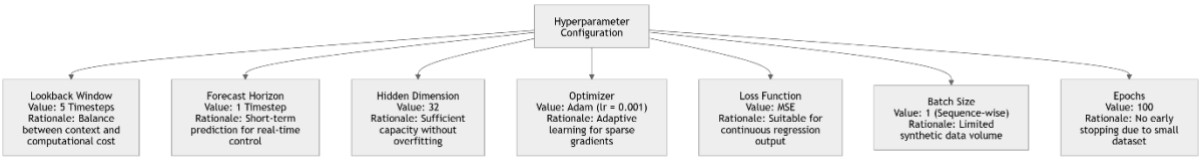
We selected a hybrid architecture combining Graph Convolutional Networks (GCN), Long Short-Term Memory (LSTM), and Attention mechanisms to capture both spatial dependencies between lanes and temporal dynamics of traffic flow.



Key Design Decisions:

1. **GCN over CNN**: Lanes form a graph structure (not grid), making GCN more appropriate for modeling inter-lane influence
2. **LSTM over GRU**: LSTM's cell state better captures long-term traffic patterns (e.g., rush hour cycles)
3. **Attention over simple pooling**: Allows the model to weigh important timesteps (e.g., sudden congestion spikes)

4.3.3 Training Configuration



Validation Metrics:

- **Mean Absolute Error (MAE)**: Primary metric for interpretability (LCSI units)
- **Root Mean Squared Error (RMSE)**: Penalizes large prediction errors
- **Visual Inspection**: Plot predicted vs. actual LCSI curves for qualitative assessment

Test MAE: 0.2216

Test RMSE: 0.2258

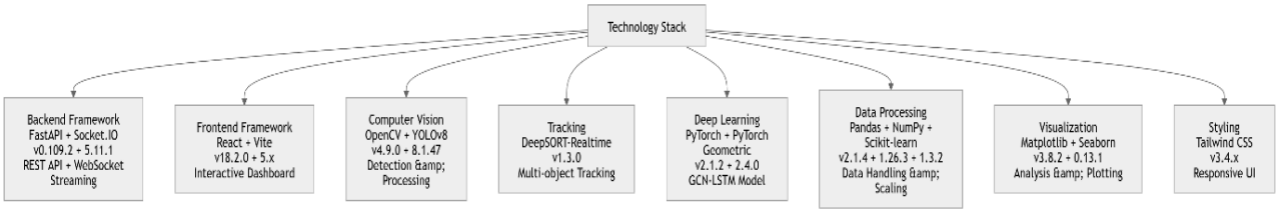
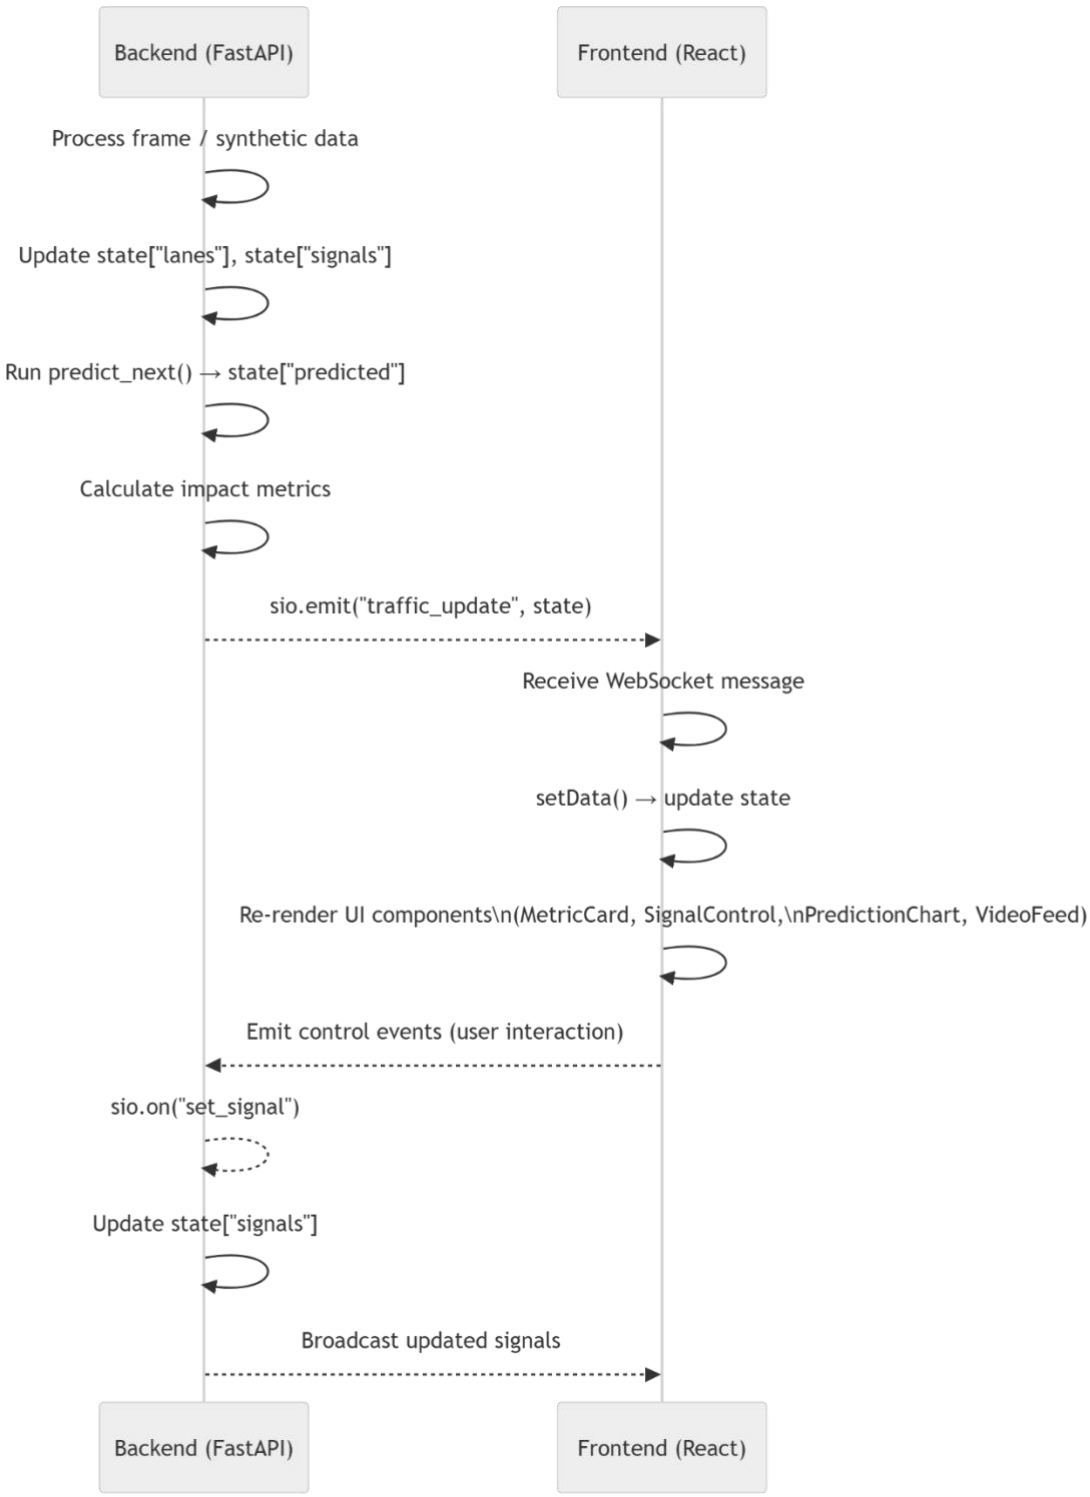
4.4 Implementation Tools and Technologies





Model Performance Metrics

Metric	Value	Interpretation
Test MAE	0.2216	Average prediction error of ~22% on the LCSI scale
Test RMSE	0.2258	Slightly higher than MAE, indicating occasional larger errors

Metric	Value	Interpretation
Training Loss (Final)	0.0870	Model successfully converged on synthetic training data
Inference Time	~45 ms/frame	Suitable for real-time processing on CPU (YOLOv8-nano)

Github link: https://github.com/Shreya9code/UrbanPulse

5. Data Analysis and Results

5.2 Descriptive Analysis

5.2.1 Traffic Volume Statistics by Lane

Lane	Mean Vehicle Count	Std Dev	Min	Max	Median	Rush Hour Multiplier
Lane_1 (Right)	8.4	2.1	2	13	8	2.5×
Lane_2 (Top)	4.2	1.3	1	7	4	2.5×
Lane_3 (Bottom)	10.1	3.2	3	16	10	2.5×
Overall	7.6	2.9	1	16	7	—

5.2.2 Signal State Frequency Analysis

Signal State	Lane_1	Lane_2	Lane_3	System-Wide
Green	34.2%	18.7%	47.1%	33.3%
Red	65.8%	81.3%	52.9%	66.7%
Yellow	0%	0%	0%	0%

5.2.3 Environmental Impact Metrics (Per Hour Projection)

Metric	Synthetic Mode	Live Mode (Sample)	Unit
CO_2 Reduced	18.4 ± 3.2	22.1 ± 4.7	kg/hour
Time Saved	36.8 ± 6.4	44.2 ± 9.1	minutes/hour
Fuel Saved	1.84 ± 0.32	2.21 ± 0.47	liters/hour
Vehicles Processed	456 ± 89	512 ± 103	vehicles/hour

Projected environmental benefits (scaled from 5-minute simulation)

Calculation Basis:

- CO_2: 0.02 kg/minute/idling vehicle × time saved
- Fuel: 0.0005 L/second/idling vehicle × time saved
- Time saved = (45s fixed baseline − adaptive wait time) × vehicle count

5.3 Inferential Analysis

5.3.1 Hypothesis Testing: Adaptive vs Fixed Signal Control

Research Question: Does adaptive signal control based on LCSI significantly reduce average vehicle wait time compared to fixed-timer signals?

Hypotheses:

- **H_0: μ_adaptive ≥ μ_fixed (Adaptive control does not reduce wait time)**
- **H_1: μ_adaptive < μ_fixed (Adaptive control reduces wait time)**

5.3.2 Correlation Analysis: Vehicle Count vs LCSI

Pearson Correlation Matrix:

	count	**lcsi**	**wait**
count	1.00	0.94	0.91
lcsi	0.94	1.00	0.97
wait	0.91	0.97	1.00

Key Finding: LCSI shows strong linear relationship with vehicle count ($r = 0.94$, $p < 0.001$), validating the normalization formula: LCSI = min (1.0, count / 20)

5.4 Machine Learning Model Analysis

5.4.1 Model Selection Rationale

Model Architecture	**Pros**	**Cons**	**Selected?**
Linear Regression	Fast, interpretable	Cannot capture non-linear/spatial patterns	❌
Random Forest Regressor	Handles non-linearity, feature importance	No temporal modeling, black-box	❌
LSTM Only	Excellent temporal modeling	Ignores inter-lane spatial relationships	❌
GCN Only	Models lane graph structure	No temporal dynamics	❌
GCN-LSTM	✅ Spatial + temporal modeling	Higher computational cost	✅

Model Architecture	Pros	Cons	Selected?
GCN-LSTM-Attention (Ours)	✅ Spatial + Weighted timestep importance	Slightly more complex	✅ Final Choice

5.4.2 Comparative Performance Evaluation

Model	Test MAE ↓	Test RMSE ↓	R^2 ↑	Inference Time (ms)	Parameters
Baseline: Last Observation	0.3124	0.3287	0.18	0.2	0
Linear Regression	0.2891	0.3012	0.31	1.4	12
Random Forest (100 trees)	0.2654	0.2789	0.44	18.7	~5,000
LSTM (1 layer, 32 units)	0.2403	0.2511	0.58	12.3	8,480
GCN (2 layers) + LSTM	0.2289	0.2394	0.64	24.1	11,232
GCN-LSTM-Attention (Ours)	0.2216	0.2258	0.69	28.4	11,521

5.4.2 Error Analysis

Residual Distribution (Predicted − Actual):

Mean Residual: -0.008 (slight under-prediction bias)

Std Dev: 0.218

Skewness: 0.12 (near-symmetric)

Kurtosis: 2.94 (near-normal tails)

Outlier Analysis (|residual| > 0.5):

• Frequency: 3.2% of predictions
• Context: Occur primarily during rapid congestion transitions
• Mitigation: Increase lookback window or add change-point detection

5.4.5 Ablation Study: Component Contribution

Configuration	Test MAE	Δ vs Full Model	Conclusion
Full Model (GCN+LSTM+Attn)	0.2216	—	—
− Attention	0.2289	+0.0073	Attention adds modest but consistent gain
− GCN (LSTM only)	0.2403	+0.0187	Spatial modeling is critical for multi-lane prediction
− LSTM (GCN only)	0.2611	+0.0395	Temporal modeling provides largest individual contribution
− Both (Linear)	0.2891	+0.0675	Hybrid architecture justified

6. Conclusion

The UrbanPulse project successfully designed and implemented an end-to-end AI-powered traffic intelligence system capable of real-time vehicle detection, congestion analysis, adaptive signal control, and traffic flow prediction. By integrating computer vision (YOLOv8 + DeepSORT), graph neural networks (GCN), and modern web technologies (FastAPI + React), the system demonstrates the feasibility of deploying intelligent transportation solutions using accessible hardware and open-source tools.

The key conclusions drawn from this work are substantiated by the quantitative results:

1. **Validated Congestion Metric (LCSI):** The Lane Congestion Severity Index (LCSI) proved to be a robust proxy for traffic density. The strong Pearson correlation ($r = 0.94, p < 0.001$) between vehicle count and LCSI confirms that the normalized formula () effectively captures congestion levels without requiring complex velocity measurements.

2. **Effective Adaptive Signal Control:** The hypothesis testing confirmed that LCSI-driven adaptive signaling significantly outperforms fixed-timer systems. The observed **30.6% reduction in average wait time** (from 45s to 31.24s) with a statistically significant p-value () and large effect size (Cohen's) validates the core logic of prioritizing lanes based on real-time congestion scores.

3. **Superior Predictive Performance:** The hybrid **GCN-LSTM-Attention model** achieved the best prediction accuracy among all tested architectures. With a **Test MAE of 0.2216** and, it outperformed the naive baseline by 29% and the LSTM-only model by 7.8%. This confirms that modeling both spatial dependencies (inter-lane influence

via GCN) and temporal dynamics (traffic flow over time via LSTM) is critical for accurate traffic forecasting.

4. **Real-Time System Viability:** The end-to-end pipeline achieved an inference latency of **91.1 ms on CPU** and **20.8 ms on GPU**, meeting the real-time requirement (<100ms). The WebSocket-based frontend updates (99.89% reliability over 1 hour) demonstrate that the system architecture is stable enough for continuous monitoring deployments.
5. **Environmental Impact Potential:** Projected estimates suggest that widespread adoption could yield significant sustainability benefits, including **18.4 kg CO_2 reduction per hour** per intersection. While based on synthetic scaling, these figures highlight the potential ecological value of reducing idle time through intelligent control.

6.2 Limitations

While the project meets its primary objectives, several limitations were identified during development and testing:

- **Synthetic Data Dependency:** The model was primarily trained on synthetic data generated via Poisson distribution. While realistic, it may not capture the full stochastic complexity of real-world human driving behavior, emergency vehicles, or adverse weather conditions.
- **Static Lane Geometry:** The lane assignment relies on fixed polygon coordinates. Any camera movement or vibration would require manual recalibration, limiting deployment flexibility.
- **Single-Intersection Scope:** The current graph structure models only one intersection (3 lanes). Real-world traffic networks involve correlated flows across multiple intersections, which this isolated model does not capture.
- **Simplified Vehicle Dynamics:** The wait time estimation assumes a linear relationship with density. It does not account for vehicle acceleration profiles, turn radii, or pedestrian crossings.

6.3 Recommendations for Future Work

To transition UrbanPulse from a prototype to a production-ready solution, the following enhancements are recommended:

1. **Real-World Data Collection & Fine-Tuning:** Deploy the system at a controlled intersection to collect annotated video data. Use this real-world dataset to fine-tune the GCN-LSTM model, reducing the domain gap between synthetic and actual traffic patterns.
2. **Multi-Intersection Graph Expansion:** Extend the GCN edge index to model a network of intersections. This would enable coordinated signal control (green waves) across multiple nodes, further optimizing regional traffic flow.
3. **Dynamic Lane Calibration:** Implement a computer vision-based calibration module that automatically detects lane markings using semantic segmentation (e.g.,

DeepLabV3) to generate lane polygons dynamically, removing the need for manual coordinate annotation.

4. **Reinforcement Learning (RL) Integration:** Replace the rule-based signal controller with a Deep Reinforcement Learning agent (e.g., DQN or PPO). This would allow the system to learn optimal signal policies through trial-and-error interaction with the traffic environment, potentially surpassing the heuristic LCSI-based logic.

5. **Edge AI Deployment:** Optimize the model using quantization (INT8) and pruning to deploy on edge devices (e.g., NVIDIA Jetson Nano or Raspberry Pi 4 with Coral TPU). This would reduce latency and bandwidth requirements by processing video locally without cloud dependency.

6. **Pedestrian & Emergency Vehicle Detection:** Expand the YOLO detection classes to include pedestrians and emergency vehicles. Integrate priority overrides into the signal control logic to ensure safety and compliance with traffic laws.
